

Imipenem

Imipenem is a beta lactamase resistant antibiotic with a broad spectrum of activity. It is a type of carbapenem that inhibits cell wall synthesis. It is always administered intravenously with cilastatin, which is an inhibitor of renal dehydropeptidase I. Without cilastatin, imipenem is susceptible to degradation by renal dehydropeptidase I in the renal tubules. This wide spectrum antibiotic can be used for gram positives, gram negatives, aerobes and anaerobes. It is especially used for pseudomonas and enterococcus infections, but is not effective against methicillin resistant staphylococcus aureus (MRSA). Clinically, imipenem's use is restricted to special cases to avoid development of bacterial resistance. This antibiotic also has many side effects such as nausea, vomiting, and seizures. Meropenem is another carbapenem with activity similar to imipenem but has reduced risk of seizures and does not require co-administration of cilastatin because it not degraded by dehydropeptidase I.

PLAY PICMONIC

Mechanism

Resistant to Beta-Lactamases

Resisting (B lac) Black Beta-fish wearing Resistance-bandana

Carbapenem antibiotics like imipenem and meropenem are resistant to beta-lactamases and can therefore cover a wide spectrum of bacterial infections.

Broad Spectrum

Broad Spectrum of Colors

Carbapenems like imipenem and meropenem cover a broad spectrum of bacteria, such as gram-positives, gram-negatives, aerobes, and anaerobes.

Indications

Anaerobes

Ant-robe

Anaerobic bacteria are bacteria that do not require oxygen for growth. This antibiotic can be used for anaerobic organisms.

Gram-Negative Rods

Graham-cracker Negative-devil with Rod

Gram-negative rods are bacteria that stain gram-negative due to a relatively thin peptidoglycan layer in the cell wall with a rod shape. Imipenem covers a broad spectrum of bacteria, including gram-negative rods.

Gram-Positive Cocci

Graham-cracker Positive-angel with Cock-eyes

Gram-positive cocci are gram-positive organisms that absorb crystal violet on gram stain due to a thick peptidoglycan layer with a spherical shape.

Gram-positive cocci include Staphylococcus and Streptococcus species. Imipenem covers a broad spectrum of bacteria, including gram-positive cocci.

Must Administer with Cilastatin

Silly-string

Imipenem can be degraded by renal dehydropeptidase I in the renal tubules and, therefore, requires co-administration with cilastatin, a dehydropeptidase I inhibitor. Meropenem, however, does not require cilastatin because it is not degraded by dehydropeptidase I.

Cilastatin is Inhibitor of Renal Dehydropeptidase I

Silly-string Inhibiting Kidney at Hydrant-pep-D

Cilastatin is always given together with imipenem to prevent imipenem's degradation by renal dehydropeptidase I.

Side Effects

Diarrhea

Toilet

Carbapenems like imipenem and meropenem are known to cause GI distress, including diarrhea, nausea, and vomiting.

Skin Rash

Skin Rash-being-examined-by-dermatolgoist

Skin rash is another occasional adverse effect caused by carbapenem antibiotics like imipenem and meropenem.

Seizures

Caesar

Seizures are a more serious adverse effect that can occur with the use of imipenem. However, meropenem has a much-reduced potential for this side effect compared to imipenem.

Considerations

Meropenem

Mirror-penny

Meropenem is another carbapenem with activity similar to imipenem but has a reduced risk of seizures and does not require co-administration of cilastatin because it is not degraded by dehydropeptidase I.

Stable to Dehydropeptidase I

Unaffected by Renal-hydrant with Peptidase-logo

Meropenem, unlike imipenem, is stable to dehydropeptidase I and, therefore, does not require co-administration of cilastatin.

Reduced Risk of Seizures (Non-Seizure Causing)

Nun Caesar

Meropenem has a reduced risk of CNS toxicity or seizures as compared to imipenem.
