

Light's Criteria

Light's Criteria is a diagnostic tool used to determine of the cause of a pulmonary effusion; transudate versus exudate. This relies on a comparison of the chemistries in the pleural fluid to those in the blood. According to Light's criteria, a pleural effusion is likely exudative if at least one of the following exists: The ratio of pleural fluid protein to serum protein is greater than 0.5, the ratio of pleural fluid LDH and serum LDH is greater than 0.6, or the pleural fluid LDH is greater than 0.6 or $\frac{2}{3}$ times the normal upper limit for serum.

Use

Determines Transudative vs. Exudative Source of Pleural Effusion

[Transparent-transudate vs. Oozing-exudate Source of Fluid around Lungs](#)

Light's criteria is used to determine whether the source of a pleural effusion is transudative or exudative.

Exudate if (At Least One of the Following):

Effusion/Serum Protein Ratio > 0.5

[Protein-ribbon Above \(0.5\) Hand](#)

If the ratio of pleural fluid protein to serum protein is greater than 0.5, the effusion fluid is exudative.

Effusion/Serum LDH Ratio > 0.6

[Lady-Horns Above \(0.6\) Horn](#)

The pleural effusion is likely exudative if the ratio of pleural fluid LDH and serum LDH is greater than 0.6

Effusion LDH > Two-thirds Upper Serum LDH Range

[Two-thirds Upper Limit with Lady-Horns](#)

If the pleural fluid LDH is greater than 0.6 or $\frac{2}{3}$ times the normal upper limit for serum, it is likely to be exudative, based on Light's criteria. Different laboratories have different values for the upper limit of serum LDH, but examples include 200 and 300 IU/L.
