

## Staphylococcus epidermidis

Staphylococcus epidermidis is a gram-positive cocci that is part of the human skin flora. This organism is usually not pathogenic, but can cause infection in patients with compromised immune systems. Staphylococcus epidermidis is also a large concern with patients with catheters or other prosthetic devices, because it is known to cause adherent biofilms that grow on the devices. Characteristically, it is a catalase-positive, coagulase-negative bacterium. Staphylococcus epidermidis can be differentiated from Staphylococcus saprophyticus, which is also catalase-positive, coagulase negative, but Staph epidermidis has a sensitivity to novobiocin. Because this organism is a component of normal skin flora, it is a common contaminant of blood cultures.

PLAY PICMONIC

### Characteristics

#### Cocci

##### Cockeyed

This bacterium has a spherical shape.

#### Gram-Positive

##### Graham-cracker Positive-angel

This organism stains positive on Gram stain due to thick peptidoglycan layer which absorbs crystal violet.

#### Catalase-Positive

##### Positive-cat

Characteristically, Staph epidermidis is catalase-positive, meaning it produces the enzyme catalase. This enzyme allows the bacterium to convert hydrogen peroxide to water and oxygen. This characteristic is helpful in distinguishing Staphylococci from catalase-negative Streptococci and Enterococci.

#### Urease-Positive

##### Positive U-eraser

This bacterium has the ability to produce urease, which hydrolyzes urea in the body to ammonia.

#### Coagulase-Negative

##### Negative Clogs

Staph epidermidis can be differentiated from other Staphylococcal organisms, such as Staph aureus, because Staph aureus is coagulase-positive, while Staph epidermidis is coagulase-negative.

#### Novobiocin-Sensitive

##### Navy-bison Sensitive-crying

Staphylococcus epidermidis is catalase- positive and coagulase-negative, but is sensitive to novobiocin. In comparison, Staphylococcus saprophyticus is novobiocin- resistant, but also catalase-positive and coagulase-negative.

#### Component of Normal Skin Flora

##### Flowers on Skin

Staphylococcus epidermidis is a gram- positive cocci that is part of the human skin flora.

#### Infects Prosthetic Devices and IV Catheters

##### Prosthetic-leg and IV

Staphylococcus epidermidis is also a large concern with patients with catheters or other prosthetic devices, such as heart valves, because it is known to cause adherent biofilms that grow on the devices.

### **Contaminates Blood Cultures**

#### [Blood on Petri-dish](#)

Because this organism is a component of normal skin flora, it is a common contaminant of blood cultures.

### **Produces Adherent Biofilms**

#### [Movie-film](#)

Staphylococcus epidermidis is also a large concern with patients with catheters or other prosthetic devices, because it is known to cause adherent biofilms that grow on the devices.
