

# Eosinophilic Esophagitis

Eosinophilic esophagitis is an allergic inflammatory condition of the esophagus that involves the infiltration of the esophageal tissue by eosinophils. This condition likely involves an allergic response to food allergens and is frequently associated with atopic disease. Eosinophilic esophagitis typically presents with dysphagia due to the narrowing of the lumen from inflammation, edema, and strictures. Diagnosis is typically made by endoscopy with biopsy demonstrating eosinophilic infiltrates in the esophageal tissue. This condition is typically unresponsive to GERD treatment and requires elimination diet and/or pharmacotherapy with proton pump inhibitors and topical corticosteroids.

## Characteristics

## History of Atopic Disease

### A-top-hat Diseased-guy

About 50% of patients with eosinophilic esophagitis also have a history of some type of atopic disease (e.g., food allergies, asthma, allergic rhinitis, eczema). While the precise mechanism is unknown, it seems like allergen mediated immune system activation is the driving force of this condition.

## Symptoms

## Dysphagia

## Dice-Fajita

Eosinophil buildup and chronic inflammation of the esophageal tissue can cause narrowing of the lumen due to swelling and/or strictures. This can lead to difficulty swallowing (dysphagia). Patients often present with dysphagia to solids as the narrowing is usually not severe enough to cause difficulties swallowing liquids.

## Diagnosis

## Endoscopy with Biopsy

### Endoscope with Biopsy-needle

Endoscopy with biopsy is the diagnostic study of choice for the confirmation of eosinophilic esophagitis. Characteristic findings on endoscopy include longitudinal mucosal furrows, fixed esophageal rings, narrowed lumen, corrugated mucosa, and strictures.<br>

### Eosinophilic Infiltrate

## Eosinophilic-Eagles In a Sarcophagus

Eosinophils are white blood cells that increase in response to allergen mediated immune system activation. In patients with eosinophilic esophagitis, eosinophils infiltrate and accumulate in the esophageal tissue. This buildup of eosinophils can lead to chronic inflammation of esophageal mucosa. Biopsy of the tissue reveals at least 15 eosinophils per high-power field infiltrating esophageal mucosa.

## Unresponsive to GERD Therapy

## Ant-acid-bottle and H2 Block-man Ignored By Girdle-Girl

GERD therapy (e.g., antacids, H-2-receptor blockers) is usually ineffective in patients with eosinophilic esophagitis. Dietary modifications (e.g., removal of the allergen) is crucial for the effective control of disease activity, and proton pump inhibitors or topical steroids can be used as initial pharmacologic agents.

## Interventions

## **Elimination Diet**

### **Food Being Eliminated**

One of the initial treatment options for eosinophilic esophagitis is elimination diet. A six-food elimination diet or a four-food elimination diet are both viable options. Foods that are eliminated typically include common allergens (e.g., dairy products, wheat, egg, soy). This approach to treatment should be coordinated with a dietician since elimination diet can result in restriction of calories and nutrients.

## **Proton Pump Inhibitors (PPIs)**

### **Proton Pump with Inhibiting-chains**

Proton pump inhibitors are one of the first-line medications for eosinophilic esophagitis. The clinical response should be evaluated after an 8-week course of treatment. At the end of the 8-week course, endoscopy is also frequently done to evaluate histologic response.

## **Topical Glucocorticoids**

### **Top-hat Quarter-on-steroids**

Topical glucocorticoids are also first-line medications for eosinophilic esophagitis. Fluticasone treatment for 4-8 weeks is typically recommended. The drug is sprayed in the back of the mouth, and the patient is instructed to swallow so that the drug coats the mucosal surface of the esophagus.
